

Project Dyeskit

Inclusive Village Wellness and Sustainable Future using AI

Summary:

Given the distinct ecological, cultural, spiritual, and socioeconomic context of Ladakh, Project DYESKIT is an innovative project that aims to create a composite, village-wise picture of wellness and happiness in the area. Over the course of four months, the project combines structured quantitative evaluation using indicator-based surveys and scoring frameworks with field-based qualitative inquiry, such as life histories, narrative interviews, observations, and community discussions. Project DYESKIT is a conceptual and analytical exercise that captures how everyday experiences of well-being in Ladakhi villages are shaped by the intersections of **physical health, financial security, emotional resilience, social cohesion, environmental harmony, intellectual engagement, and spiritual life**. It is more than just a data repository. **The Village Well-Being Index (VWBI)**, which uses a 7-point Likert scale ranging from **Foundational Support Needed to Thriving Well-Being**, systematically measures these **seven dimensions** with equal weighting across dimensions and **28 indicators**.

The project's translation of multi-layered qualitative and quantitative data into a generative AI-enabled analytical framework is a major innovation that distinguishes DYESKIT from a conventional survey. AI is proposed not as a cosmetic layer, but as the analytical engine that can connect structured scores, village narratives, geospatial and contextual information, and interpretive notes into usable village-level insights. This method maintains the diversity and importance of lived experience while enabling evidence-based interpretation, comparison, querying, and planning support.

Project DYESKIT is urgently needed in Ladakh now because the region is undergoing simultaneous ecological, economic, infrastructural, and cultural transitions without a sufficiently integrated village-level evidence system to understand their combined effects. Climate stress, water insecurity, tourism-led development, changing livelihoods, youth aspirations, health access gaps, and weakening traditional support systems are being experienced together, but are often measured separately or anecdotally. Without a structured and locally grounded assessment, planning risks becoming reactive, sector-wise, and disconnected from village realities.

If this gap is not addressed, Ladakh could face interventions that overlook early signs of social stress, livelihood vulnerability, environmental degradation, and cultural erosion. Villages may be treated as administratively similar even when their risks, strengths, and adaptive capacities differ sharply. DYESKIT responds to this missing layer by creating a timely, multidimensional knowledge base that can guide climate-responsive, culturally sensitive, and community-centered development before pressures become harder to reverse.

Rationale

Ladakh is at a point where decisions made in the next few years will strongly shape village futures. Climate change, increased infrastructure development, tourism growth, market integration, and shifting

aspirations are already altering water systems, agriculture, mobility, housing, education, health access, and cultural life. Traditional modes of resilience that evolved for a fragile mountain ecosystem remain important, but they are being tested by pressures that are faster, more interconnected, and less predictable than before.

What is missing at present is a village-wise, multidimensional evidence base that can show how these pressures interact in everyday life. Existing information is often sectoral, scattered, or focused on infrastructure and income alone. It does not adequately capture the connections between environmental stress, livelihood change, physical and mental health, social cohesion, education, cultural continuity, and spiritual well-being.

If this gap remains unaddressed, development planning may miss early warning signs, duplicate efforts, or prioritize visible infrastructure while overlooking hidden vulnerabilities. Water scarcity, declining agricultural productivity, dependence on fragile income sources, waste and sanitation stress, mental health pressures, and erosion of cultural practices can compound over time. Project DYESKIT therefore provides a timely tool for understanding not only whether villages are progressing, but also where resilience is weakening and where support is most urgently needed.

Conceptualization of Project Dyeskit:

The principles behind Project DYESKIT are inspired by widely recognized models that go beyond simply looking at income to measure development. **These include Bhutan's Gross National Happiness (GNH) Survey and the UNDP's Multidimensional Poverty Assessment.** These approaches all have the underlying concept that **human well-being is inherently multi-dimensional and is shaped by physical circumstances as well as social, emotional, environmental, cultural, and spiritual factors.**

Inspired by these models, Project DYESKIT is conceptualized to adapt and reinterpret their fundamental principles according to **Ladakh's unique ecological, cultural, and socioeconomic circumstances.** **Conventional development assessments are unable to adequately capture the context-specific framework required for high-altitude geography, extreme weather conditions,** fragile ecosystems, vibrant spiritual traditions, close-knit village institutions, and rapidly changing livelihood systems.

Accordingly, DYESKIT defines village well-being as an integral and interconnected state in which people's interactions with their surroundings, community, culture, and belief systems contribute to wellness. **Each of the seven dimensions used in the project represents a crucial area of lived experience in Ladakhi villages:**

The Seven dimensions are: -

1. **Physical**
2. **Social**
3. **Financial**

4. Emotional
5. Environmental
6. Intellectual
7. Spiritual

Each dimension is measured through **four carefully chosen indicators**, leading to a total of **28 indicators** that collectively offer a comprehensive picture of village wellness. **The indicators are designed to be locally understandable, quantitatively measurable, and culturally relevant, ensuring that intangible ideas such as resilience, harmony with nature, ethical living, and community cohesion are translated into tangible and measurable realities.**

	Dimensions	Indicators
1	Physical	4
2	Social	4
3	Financial	4
4	Emotional	4
5	Environmental	4
6	Intellectual	4
7	Spiritual	4
	Total	28

Table 1. Overview of Village Wellness Dimensions and Indicators

In Contrast to deficit-focused approaches, **Project Dyeskit emphasizes strength, capacities and adaptive practices alongside areas requiring supports.** The framework considers spiritual practice, ecological balance, and intergenerational social relations on an equal footing with health, education, and livelihoods because it acknowledges that well-being in Ladakh cannot be separated from these aspects.

The conceptual framework of DYESKIT enables comparison between villages and time, while allowing for nuanced local understanding through the integration of qualitative narratives and quantitative scoring into a Village Well-Being Index (VWBI). By doing this, the project creates a model for evaluating well-being in high-altitude mountain areas that is context-responsive, morally sound, and pertinent to policy. This model helps with both local development planning and more general national and international conversations about sustainable and holistic development.

Purpose and Objectives of Project DYESKIT

Project DYESKIT seeks to provide a comprehensive, context-sensitive, and empirically informed knowledge of village-level wellbeing in Ladakh. Moving beyond single-dimensional development measures, the initiative aims to capture the interrelated physical, social, environmental, intellectual, economical, emotional, and spiritual elements of well-being as they are experienced and understood in

Ladakh communities. The effort aims to improve the knowledge foundation for sustainable, climate-responsive, and community-centered development planning in one of India's most environmentally sensitive Himalayan areas.

Objectives

The Project Dyeskit pursue the following overarching objectives:

1. To develop an empirically grounded, seven-dimension wellness framework for Ladakh's villages
 - o Interpret each dimension (spiritual, environmental, physical, emotional, intellectual, financial, social) in specific village contexts.
 - o Co-construct indicators in dialogue with communities and the project team.
2. To generate a robust body of qualitative and quantitative data on village-level wellness insights
 - o Produce narrative, observational, and survey-based material that captures local articulations of wellness.
 - o Ensure methodological rigor, ethical practice, and cultural sensitivity in fieldwork.
3. To organise and analyse data in a transparent, reusable form
 - o Create a clean, well-documented database cum knowledge bank capable of supporting further analytical work.
 - o Systematize qualitative material through thematic and contextual organization.
4. To construct village-wise and dimension-wise wellness scores
 - o Develop an internally consistent scoring framework that reflects the seven dimensions.
 - o Enable individual village insights and comparison across villages while retaining sensitivity to local specificities.
5. To integrate findings into an AI-enabled dashboard and analytical environment
 - o Provide structured inputs (indicators, metadata, interpretive notes) for interactive, analytic visualization and AI-assisted analysis.
 - o To undertake SWOT and predictive analysis grounded at village or cluster level.
 - o Explore emerging patterns and associations to inform plausible future trajectories of village wellness.
6. To contribute to a comprehensive Ladakh's Village Wellness Atlas document
 - o Produce village profiles, analytical narratives, and interpretive sections suitable for academic, policy making and institutional use.

AI-Enabled Analytical Framework

The AI component is a central part of Project DYESKIT, not an add-on after data collection. Without this layer, the project would largely remain a survey and documentation exercise. The AI-enabled framework is intended to convert field data into an interactive knowledge system that can support interpretation, comparison, and decision-making across villages.

Data integration: combine quantitative indicator scores, qualitative narratives, field notes, metadata, and contextual village information into a structured analytical base.

Village-level querying: allow users to ask natural-language questions such as which villages show stress in water security, where livelihood diversity is weak, or how environmental conditions relate to health and emotional well-being.

Pattern recognition and comparison: identify recurring relationships, outliers, and cluster-level patterns across the seven dimensions while keeping the original data traceable.

Decision support: generate explainable insights for planning, prioritization, dashboard visualization, SWOT analysis, and future scenario-building.

Cultural and ethical safeguards: ensure AI outputs remain grounded in verified field evidence, include interpretive cautions, and do not replace community validation or human judgment.

In this sense, AI allows DYESKIT to move from data collection to knowledge translation. It helps convert village experience into accessible insights for researchers, planners, institutions, and community-facing development work, while keeping the local context and qualitative depth visible.

Dimensions and indicators

This section explains the seven dimensions and 28 indicators of Village Well Being Index (VWBI).

1. Physical Well Being

The Physical Well-Being dimension covers people's physical health and functional capabilities, as well as the structural factors that permit or limit health in a community. In Ladakh, physical well-being is heavily impacted by high-altitude life, harsh meteorological circumstances, seasonal isolation, inadequate medical facilities, and shifting food and livelihood patterns. This dimension so defines health not just as the absence of sickness, but also as an individual's ability to sustain strength, mobility, and resilience in daily life, aided by accessible and dependable healthcare services.

This dimension will be assessed through four interrelated indicators to get a holistic picture of Physical Well-being. The four selected indicators are:

I. Nutritional BMI

The first indicator, **Body Mass Index Nutritional Status (BMI)**, determines whether individuals can achieve a healthy balance between food intake and physical requirements.

How an individual attains adequacy in this indicator is determined as follows:

- a) Normal range = **1 (Adequacy Achieved)**
- b) Mild under/over nutrition = **0.5 (Partial Adequacy Achieved)**
- c) Severe malnutrition/obesity = **0 (No Adequacy Achieved)**

II. Chronic or High-altitude illness

- a) No chronic illness (BP, diabetes, asthma) = 1
- b) Managed with medication = 0.5
- c) Unmanaged/severe = 0

III. Access to health Care

- a. Health center within village / regular mobile health camps = 1
- b. Health facility within 10–20 km = 0.5
- c. Beyond 20 km / seasonal access only = 0

IV. Physical Activity and Functional Ability

- a. Active daily work (farming, walking, livestock, labor) = 1
- b. Moderate activity = 0.5
- c. Sedentary / physically restricted = 0

2. Financial Well-Being

This dimension seeks to analyze and understand financial well-being in terms of stable income sources, livelihood opportunities and diversity, ownership of assets, and savings.

Indicators

I. Primary Income Source

- a. Stable (govt job, pension, sustainable tourism, business, farming + livestock) = 1
- b. Seasonal/irregular = 0.5

- c. No stable income = 0

II. Income Sufficiency

- a. Meets household needs year-round = 1
- b. Meets basic needs but no buffer = 0.5
- c. Insufficient = 0

III. Savings / Assets

- a. Savings, land, livestock, or SHG membership = 1
- b. Limited savings/assets = 0.5
- c. None / indebted = 0

IV. Livelihood Diversity

- a. More than one income source = 1
- b. Single source = 0.5
- c. No clear livelihood = 0

3. Emotional Well-Being (Mental Health & Resilience)

This dimension seeks to understand the emotional and mental states of individuals, including emotional stability, psychological well-being, and the availability of support systems.

Indicators

I. Self-Reported Emotional State

- a. Calm, positive, hopeful = 1
- b. Occasional stress/anxiety = 0.5
- c. Persistent distress/depression = 0

II. Stress Management

- a. Uses healthy coping (prayer, walking, sharing, art) = 1
- b. Limited coping = 0.5
- c. No coping mechanisms = 0

III. Family & Social Support

- a. Strong emotional support system = 1
- b. Partial support = 0.5
- c. Isolated = 0

IV. Substance Dependence (Alcohol/Smoking)

- a. None = 1
- b. Occasional = 0.5
- c. Regular dependence = 0

4. Social Well-Being (Community & Cultural Strength)

This domain seeks to understand social aspects, including the strength of cultural traditions, gender and social inclusion, and overall social bonding within the community.

Indicators:

I. Participation in Community Activities

- a. Regular participation (festivals, village meetings, religious events) = 1
- b. Occasional = 0.5
- c. None = 0

II. Social Trust & Safety

- a. High trust, low conflict = 1
- b. Moderate trust = 0.5
- c. Frequent conflict / insecurity = 0

III. Gender & Social Inclusion

- a. Equal participation of women & marginalized groups = 1
- b. Partial inclusion = 0.5
- c. Exclusion/discrimination = 0

IV. Inter-Generational Bonding

- a. Elders respected, youth engaged = 1
- b. Weak connections = 0.5
- c. Breakdown of relations = 0

5. Environmental Well-Being

Purpose: Measure harmony with Ladakh's fragile ecosystem.

Indicators

I. Water Security

- a. Reliable clean water year-round = 1
- b. Seasonal scarcity = 0.5
- c. Severe shortage/contamination = 0

II. Waste & Sanitation Practices

- a. Proper waste segregation & toilets = 1
- b. Partial management = 0.5
- c. Open dumping/open defecation = 0

III. Food Quality & Local Produce

- a. Regular consumption of local, organic food = 1
- b. Mixed (local + packaged) = 0.5
- c. Mostly packaged/poor nutrition = 0

IV. Climate Resilience Practices

- a. Glacial protection, water harvesting, eco-housing = 1
- b. Some adaptation = 0.5
- c. No adaptation measures = 0

6. Intellectual Well- Being

This dimension comprises formal education level and learnings of individuals in a community and their awareness regarding civic sense, rights and duties.

Indicators

i. Educational Attainment

- a. Higher secondary & above = 1
- b. Primary/secondary = 0.5
- c. No formal education = 0

ii. Continuous Learning

- a. Actively learning new skills/knowledge = 1
- b. Occasional learning = 0.5
- c. No learning engagement = 0

iii. Digital & Media Literacy

- a. Can access & evaluate information = 1
- b. Limited digital use = 0.5
- c. Digitally excluded = 0

iv. Environmental & Civic Awareness

- a. Aware of rights, duties, climate issues = 1
- b. Partial awareness = 0.5

- c. Unaware = 0

7. Spiritual Well-Being

This domain focuses on assessing and measuring spiritual dimensions of life, including overall life satisfaction, adherence to ethics and values, and a sense of inner peace and contentment.

Indicators

I. Spiritual Practice

- a. Regular prayer/meditation/rituals = 1
- b. Occasional = 0.5
- c. None = 0

II. Sense of Purpose

- a. Strong life purpose & direction = 1
- b. Unclear purpose = 0.5
- c. Hopelessness = 0

III. Ethical Living

- a. Decisions guided by ethics & karma = 1
- b. Sometimes = 0.5
- c. Rarely = 0

IV. Inner Peace & Contentment

- a. Mostly peaceful & content = 1
- b. Fluctuating = 0.5
- c. Persistent dissatisfaction = 0

Indexing and Weightage

All seven dimensions are assigned equal weight, with each dimension carrying a weight of $1/7$ (**14.28%**). Each dimension consists of **four indicators**, and therefore each indicator carries an equal weight of $1/28$ (**3.57%**) of the total index.

Well-Being Index (WBI): How the Points Are Determined

The **Village Well-Being Index (WBI)** measures overall well-being using **7 dimensions**, and it is expressed on a **7-point Likert scale**, where:

- **1 = Very Low Well-Being**
- **7 = Very High Well-Being**

Step 1: Percentage Score for Each Dimension

Each dimension (for example Physical Well Being, Social Well Being, Educational Well Being etc.) is first calculated as a percentage score (0–100%) based on adequacy points/percentage scored in each indicator. For example, **if adequacy is achieved in one indicator, the percentage accumulated for that indicator will be equal to 3.5%, for partial adequacy it is 1.75%** and in case of **No adequacy achieved will be 0%**. If all the indicator achieves adequacy, then the dimension score in percentage would be 100%. Which means the sum percentage of all the indicators is 14.28 % which is the total weightage assigned to that dimension.

Example:

- Health dimension score = **68%**
- Education dimension score = **82%**

Step 2: Convert Percentage into a 1–7 Likert Point Scale

Each dimension's percentage score is converted into a **Likert scale point (1 to 7)** using predefined ranges.

Percentage to Likert Scale Conversion

Percentage Range	Likert Point	Meaning/Interpretations
0–14%	1	Foundational Support Needed Basic well-being systems are at an early stage; strong institutional and programmatic support is needed.
15–28%	2	Emerging Well-Being Initial structures exist, but several dimensions need strengthening and consistent support.
29–42%	3	Developing Well-Being Progress is visible; however, access and quality across dimensions remain uneven.

43–56%	4	Basic Well-Being Achieved Minimum standards are met; the village is stable but has clear scope for improvement.
57–70%	5	Advancing Well-Being Most households experience reliable services and livelihoods; conditions are improving steadily.
71–84%	6	Strong Well-Being High performance across dimensions with good resilience and social cohesion.
85–100%	7	Thriving Well-Being The village demonstrates holistic, inclusive, and sustainable well-being outcomes.

Example:

- 68% → Likert Point = 5
- 82% → Likert Point = 6

This process is repeated for **all 7 dimensions**.

Step 3: Calculate the Final WBI Score

Once all dimensions are converted into Likert points:

1. **Add the Likert points of all dimensions**
2. **Divided by the total number of (7)**

Figure 1: Flow chart indicating Well Being Points

dimensions

Step 4: Final VWBI Interpretations

The final WBI value will always lie between **1 and 7**.

Example Calculation

Dimension	Likert Point
D- 1	5
D- 2	6
D- 3	4
D- 4	5
D-5	6
D-6	5
D- 7	4

Total = 35

WBI=35/7=5.0

Interpretation:

- **WBI = 5.0** indicates:

Advancing Well-Being

Overall Village Well Being Index (VWBI)

Well, Being Index (WBI)/Total Number of people Surveyed.

If VWBI = 5.0 which indicates:

Advancing Well-Being

Most households experience reliable services and livelihoods; conditions are improving steadily

Methodology and Data Collection

Research Tools and Data Collection Strategies

Data collection will involve a combination of qualitative and quantitative tools, including:

- Household or individual surveys, structured around the seven dimensions of wellness, to generate quantitative data that can be analyzed and compared across villages.
- Key informant interviews with local leaders, spiritual figures, health workers, teachers, women's group members, youth representatives, and other relevant actors to explore interpretive understandings of wellness and community life.
- Focus group discussions with specific constituencies (e.g., women, youth, elders) to elicit collective perspectives and intra-community diversity of experience.
- Participant observation and field notes, documenting everyday practices, spaces of interaction, and environmental conditions relevant to each dimension.

Narrative and case study documentation, capturing life histories or critical events that illuminate complex interactions between the seven dimensions.

1.3 Sampling and Village Selection

The project will select a set of villages in Ladakh that, taken together, reflect variation in geography, accessibility, and socio-economic and cultural characteristics. Within each selected village, a purposive but structured approach to sampling will be adopted to ensure that:

- Different social groups and age cohorts are represented.
- Relevant institutional actors and knowledge holders are included in qualitative components. The exact number of households and participants per village will be determined based on feasibility during the four-month window and the need to maintain depth as well as breadth.

1.4 Data Management and Analytical Procedures

Quantitative data will be entered into a structured database and subjected to systematic data cleaning (checking for consistency, missing values, outliers, and coding errors). Descriptive statistics and simple cross-tabulations will be used to explore associations between indicators and dimensions.

Qualitative materials (interview transcripts, field notes, and narrative accounts) will be organized using a coding scheme aligned with the seven dimensions, along with emergent themes identified inductively from the field. Thematic analysis will be used to:

- Interpret how villagers themselves conceptualise wellness; and
- Provide explanatory depth for quantitative patterns.

1.5 Construction of Wellness Scores and Analytical Products

Based on the cleaned and organized dataset, the project will develop:

- Village-wise overall wellness scores, reflecting the combined contribution of all seven dimensions; and
- Dimension-wise scores for each village, enabling comparative analysis of strengths and deficits.

The scoring framework will be technically transparent: each score will be derived from clearly defined and documented indicators and transformation rules. The research team will collaborate with technical partners to format this data for integration into an AI-enabled dashboard, which will support interactive visualization and exploratory analysis.

1.6 SWOT and Predictive Analysis

Drawing on both the statistical and qualitative analyses, the project will undertake SWOT analysis (Strengths, Weaknesses, Opportunities, Threats) for each village or cluster of villages. This exercise will be grounded in empirical findings and will identify factors that appear to support or undermine wellness along different dimensions.

In parallel, exploratory predictive analysis will be conducted to examine possible relationships between selected indicators and overall or dimension-specific wellness scores. The aim is not to produce definitive causal claims but to identify plausible trajectories and areas where targeted interventions might most effectively enhance village wellness.

2. Resource Requirements

The successful implementation of the Project Dyeskit over a four-month period will require a defined set of human, material, and logistical resources.

2.1 Human Resources

- Research Team
 - A small core team responsible for conceptual guidance, methodological oversight, data architecture, and final synthesis.
 - Two field-based researchers working full-time in Ladakh, responsible for village-level data collection, field documentation, preliminary analysis, and liaison with local stakeholders.
 - Technical Support
 - Data management and analytical support for structuring the database, generating wellness scores, and preparing inputs for the AI-enabled dashboard.
 - Local Facilitation
 - Where required, short-term engagement of local facilitators or interpreters to assist with community entry, translation, and coordination.

2.2 Material and Logistical Resources

- Fieldwork Logistics

- o Travel to and within Ladakh (inter-village transport, where needed).
- o Accommodation and subsistence for research personnel in village locations and at the regional base.
- o Communication facilities for coordination and reporting.
- Research Infrastructure
 - o Data collection tools (e.g. printed questionnaires, tablets/phones if digital data capture is used, stationery).
 - o Audio recording devices for interviews and focus groups (where consent is obtained).
 - o Laptops and secure digital storage for data entry, cleaning, and analysis.
- Dashboard and Analytical Tools
 - o Software and technical infrastructure required for creating and hosting the AI-enabled dashboard and performing statistical and qualitative analysis (e.g. spreadsheet and statistical packages, qualitative analysis software where applicable).

2.3 Financial Requirements

BUDGET ESTIMATE			
S.N O	Resources	Amount	Budget
1.	Field based researcher Team (2 months)	4 members	INR 2,00,000
2.	Technical Engineer Support	2 members	INR 4,00,000
3.	Tech and software support	Platforms/devices	INR 4,00,000
4.	Fieldwork Logistic	Field-related operational expenses (Travel, accommodation)	INR 1,00,000
5.	Local Facilitation	Facilitation of village-level interactions	INR 50,000
6.	Contingencies	Operational expenses and minor administrative costs	INR 50,000
TOTAL		INR 12,00,000	

(All amounts are in Indian Rupees)

3. Structure of the Work

The work of the project is organized around four interconnected components.

3.1 Village-Level Inquiry Across Seven Dimensions

The first component centers on village-level inquiry. Individuals will spend extended periods in villages in different parts of Ladakh, engaging with residents in order to understand wellness as they themselves define and experience it.

Within each of the seven dimensions—spiritual, environmental, physical, emotional, intellectual, vocational, and social—individuals will contribute to:

1. Contextual interpretation of each dimension in specific village settings (e.g., how spiritual wellness is expressed through local institutions, rituals, or everyday practices; how environmental wellness is perceived in relation to water, land, or climate).
2. Co-construction of indicators, in dialogue with the project team and communities, that can be meaningfully observed and measured.
3. Generation of qualitative material (interviews, narrative accounts, field notes, community conversations) that captures nuance and diversity of experience.
4. Administration of structured instruments, such as household or individual surveys, designed to yield quantitative data aligned with the seven-dimension framework.

This component positions the individuals as thoughtful participant-observers, attentive to both empirical regularities and subtle local variations.

3.2 Data Architecture, Curation, and Analysis:

The second component concerns data architecture and analytical preparation. Given that the final Atlas must be robust enough to support further analysis and AI-assisted tools, particular attention is given to how data are structured and curated.

Within this component, individuals will be involved in:

1. The organization and cleaning of quantitative data, ensuring that each variable is clearly defined, consistently coded, and appropriately linked to specific dimensions and villages.
2. The systematization of qualitative materials through basic coding schemes, thematic annotations, and linking of narratives to particular dimensions or village contexts.
3. The creation of intermediate analytical artefacts (such as simple cross-tabulations or dimension-wise summaries) that feed into later scoring and predictive models.

The emphasis here is on methodological transparency and traceability: every score, dashboard visualization, or predictive statement should be linked back to a clearly documented body of data.

3.3 Wellness Scoring, Atlas Profiles, and AI-Enabled Dashboard

The third component brings together the data into village-wise profiles and scores and prepares them for inclusion in an AI-enabled dashboard.

Figure C Dashboard Mock-Up & Timeline

A chatbot that can answer any questions you have about the village in a natural conversational form. Advanced and frontier models through an API will be used. In the long term, we can also train our own models to work in the Ladakhi language; however, it will require more resources.

This involves:

1. Contributing to the design and refinement of a scoring framework that yields:
 - o an overall village-wise happiness/wellness score, and
 - o separate scores for each of the seven dimensions (spiritual, environmental, physical, emotional, intellectual, vocational, and social). Translating the field evidence into structured inputs that can be ingested by an AI-enabled dashboard, including:
 - clearly labelled indicators;
 - basic metadata (village characteristics; data collection context);
 - notes on data quality and interpretive cautions.

Participating in the conceptual design of dashboard visualizations (for example, maps of village scores, radar diagrams of dimension-wise profiles, or time-insensitive comparative displays), in collaboration with the project's technical team. The objective of this component is not merely to create attractive graphics but to ensure that the complexity of the seven-dimension framework survives the transition into digital and AI-assisted formats.

3.4 SWOT and Predictive Analysis

The fourth component concerns strategic interpretation:

1. Village-level or cluster-level SWOT formulations, in which strengths, weaknesses, opportunities, and threats are derived directly from the combined qualitative and quantitative findings.
2. Exploratory predictive analysis, in which emerging associations between variables and dimensions are examined—for example, how certain vocational patterns might interact with emotional or social wellness, or how environmental conditions may correlate with physical or spiritual indicators.
3. The development of narrative explanations for these patterns that are empirically grounded yet sensitive to local histories, institutions, and political contexts.

This component aims to move beyond description, inviting fellows to engage in careful, non-speculative inference about possible trajectories of village wellness under different conditions.

4. Qualifications and skills required.

1. The program seeks two fellows who can inhabit the role of researcher, listener, analyst, and interlocutor between data and community.
2. The indicative profile includes
 1. Academic background
 - A degree at the master's level (completed or in progress) in political science or a cognate discipline in the social sciences (such as sociology, development studies, public policy, social work, anthropology, or psychology), with demonstrable engagement with empirical research.
 2. Methodological orientation
 - Familiarity with both qualitative and quantitative approaches, and readiness to work within a mixed-methods design.
 - Interest in indicator design, basic statistical description, and thematic analysis of texts or narratives.
 3. Substantive interests
 - Engagement with questions of well-being, governance, community life, and social change, broadly construed.
 - Curiosity about how spiritual, environmental, and social dimensions intersect with more conventionally studied themes such as livelihoods, institutions, and political participation.
 4. Field readiness and emplacement
 - Willingness to spend extended periods in village settings in Ladakh, including in high-altitude and climatically demanding conditions.
 - Openness to learning from local knowledge systems, community practices, and region-specific understandings of wellness.
 5. Communication and language
 - Strong written and analytical proficiency in English for documentation and reporting.

- Functional competence in Hindi for field interactions is highly desirable; familiarity with local languages or dialects will be an advantage where present.
1. The project is designed for candidates who are academically inclined and reflective, and who view fieldwork not as a logistical burden but as a central site of knowledge production.

5. Duration, Location, and Research Environment

Duration: four months, aligned with the core period of fieldwork and primary analysis for the Project Dyeskit.

Number of positions: Two Location: The primary field sites will be villages in Ladakh, with intermittent periods of desk-based work (for data organization and analysis) at a designated base within the region.

Research environment: Individuals will work in close coordination with the Atlas project team, which will provide overall conceptual guidance, methodological support, and integration of field findings into the larger program architecture.

6. Outputs and Contributions

By the end of the four-month timeline, fellows are expected to have contributed substantively to:

1. A clean, well-documented dataset (qualitative and quantitative) for the villages assigned to them, organized according to the seven dimensions of wellness.
2. A set of village-wise wellness scores and corresponding dimension-wise scores, developed within the agreed analytical framework.
3. Inputs to an AI-enabled dashboard, including indicators, data structures, and interpretive notes.
4. A series of village or cluster profiles that weave together numerical scores, narrative fragments, and contextual explanation.
5. A SWOT and predictive analysis portfolio that synthesizes key patterns and suggests plausible trajectories or areas of concern for village wellness.
6. Contributions to the drafting of sections of the Project Dyeskit, in an academic register suitable for circulation among researchers, practitioners, and institutions.

7. Future Scope

The scope of the proposed research may be extended to cover all **113 villages in Leh, Ladakh**, and, in subsequent phases, scaled to include **the full set of 256 villages across the Union Territory of Ladakh**. Such an expansion would enable a more comprehensive and region-wide understanding while retaining the original analytical framework.
